

Homework 4: Perceptron

Jef Harkay

November 17, 2011

1 Perceptron

The Perceptron algorithm I implemented was similar to Wikipedia's entry, but I had to first read in the x values and the deltas given in the homework assignment. The deltas are the correct classifications on each line (either a 1 or 0).

```
array( $x$ )  $\leftarrow$  read( $x\_values$ )
array( $deltas$ )  $\leftarrow$  read( $delta\_values$ )
array( $weights$ )  $\leftarrow$  0
 $threshold$   $\leftarrow$  0
while TRUE do
   $adjust$   $\leftarrow$  0
  for  $i = 0 \rightarrow size(x)$  do
     $sum$   $\leftarrow$  0
    for  $j = 0 \rightarrow size(x[i])$  do
       $sum \leftarrow sum + weights[j] * x[i][j]$ 
    end for

     $sum \leftarrow sum - 12$ 
    if  $sum > threshold$  then
       $gamma \leftarrow 1$ 
    else
       $gamma \leftarrow 0$ 
    end if

     $error \leftarrow deltas[i] - gamma$ 
    if  $error \neq 0$  then
       $adjust \leftarrow adjust + 1$ 
    end if

    for  $j = 0 \rightarrow size(x[i])$  do
       $weights[j] \leftarrow weights[j] + alpha * x[i][j] * error$ 
    end for
  end for
  if  $adjust$  is 0 then
    exit
  end if
end while
```

This algorithm shows the linear separator method. For part 2 of the homework, I implemented a logistic regression equation. The only thing that really changes is what the sum is, which becomes:

$$sum = 1/(1 + e^{-(array(weights)*array(x))})$$

The sum is still checked against a threshold, and the weights are computed the same—we just have a new function we’re working with.

By tweaking the learning rate, the results can vary quite a bit. To get weight values close to what the professor got, a 0.2 learning rate was used.

2 Results

Figure 1: Linear: learning rate = 1

Figure 2: Logistic: learning rate = 1

Figure 3: Linear: learning rate = 0.5

Figure 4: Logistic: learning rate = 0.5

Figure 5: Linear: learning rate = 0.2

Figure 6: Logistic: learning rate = 0.2

Figure 7: Linear: learning rate = 0.1

Figure 8: Logistic: learning rate = 0.1

3 Discussion

As you can see, the linear separator function converges a lot quicker than the logistic regression. However, when the learning rate is changed for the linear separator, the results can vary quite a bit. Whereas logistic regression seems to just hone in on one answer. Also, when the learning rate gets smaller for logistic regression, there are a lot more runs involved. I'm assuming that's because it's trying to create more precise weights.

I don't really see the advantage of one over the other with this simple example. I'm thinking if the equation was more complex, logistic regression could solve it no problem, but the linear separator might have a hard time converging to an answer.

4 Perl script

```

C:\Windows\system32\cmd.exe
Usage:
  perl ./1 perceptron.pl

Options:
  -class
    The classifier that you want to use, either type "linear" or
    "logistic".

  -learn
    The learning rate that you would like to use. Value is between 0 and
    1.
  
```

Figure 9: perceptron.pl usage

5 Code
